# Anytime Planning for IPC 2008

IPC 2008 requirement: find best possible plan within 30 minutes.  
This suggested an **anytime approach**:

- Find a solution as quickly as possible  
(any solution is better than none).  
~> greedy best-first search
- While there is still time, try to improve the solution.  
~> weighted A\* with decreasing weights

## Interesting finding:

A series of **independent runs** of weighted A\* seemed to perform better than one **continued** search.

# Continued WA\*

Basic algorithm:

- 1 Set **weight** and **bound**  
bound = cost of best known solution, initially  $\infty$
- 2 Update open list w. r. t. weight if necessary
- 3 Conduct WA\* search, using bound for pruning
- 4 Upon new best solution: report solution, goto 1.

Variants used in literature:

- Anytime A\* (Zhou & Hansen 2001, 2004)
- ARA\* (Likhachev et al. 2003)

# Example: Blocksworld Task 11-2

Plan lengths found over time:

● GBFS + <b>iterated</b> WA*:	72	50	46	36	34
● GBFS + <b>continued</b> WA*:	72	68	46	38	34

Plan qualities (best length / current length):

	9.6	8.0	<b>g1</b> <b>x</b>	8.0	9.8	8.0	8.0

# The Problem: Low- $h$ Bias

$f'$ -values,  $w = 2$

**x** expanded states

○ states in open list

		10.6	9.6	8.6 x	S x	9.0	
		9.8	8.8 x				12.0
	9.2	8.2	8.2 x	8.2	7.8	9.0	10.0
10.2	7.6	7.6	7.6 x	7.6	7.8	7.0	8.0
10.2	8.6	7.0	7.0 x	7.0	8.8	7.0	g2
	9.6	8.0	g1 x	8.0	9.8	8.0	8.0

# The Problem: Low- $h$ Bias

$f'$ -values,  $w = 2$

**x** expanded states

○ states in open list

must expand for optimal path

		10.6	9.6	8.6 x	S x	9.0	
		9.8	8.8 x				12.0
	9.2	8.2	8.2 x	8.2	7.8	9.0	10.0
10.2	7.6	7.6	7.6 x	7.6	7.8	7.0	8.0
10.2	8.6	7.0	7.0 x	7.0	8.8	7.0	g2
	9.6	8.0	g1 x	8.0	9.8	8.0	8.0

# The Problem: Low- $h$ Bias

$f'$ -values,  $w = 2$

must expand for optimal path

but many open states have lower  $f'$ -value

		10.6	9.6	8.6	S	9.0	
		9.8	8.8				12.0
	9.2	8.2	8.2	8.2	7.8	9.0	10.0
10.2	7.6	7.6	7.6	7.6	7.8	7.0	8.0
10.2	8.6	7.0	7.0	7.0	8.8	7.0	g2
	9.6	8.0	g1	8.0	9.8	8.0	8.0

# The Problem: Low- $h$ Bias

$f'$ -values,  $w = 1.5$  (reduced weight)

$\rightsquigarrow$  search less greedy

		8.7	7.7	6.7 x	S x	7.0	
		8.1	7.1 x				10.5
	7.9	6.9	6.9 x	6.9	6.85	8.0	9.0
8.9	6.7	6.7	6.7 x	6.7	6.85	6.5	7.5
8.9	7.7	6.5	6.5 x	6.5	7.85	6.5	g2
	8.7	7.5	g1 x	7.5	8.85	7.5	7.5

# The Problem: Low- $h$ Bias

$f'$ -values,  $w = 1.5$  (reduced weight)

$\rightsquigarrow$  search less greedy

but effect still persists

		8.7	7.7	6.7 x	S x	7.0	
		8.1	7.1 x				10.5
	7.9	6.9	6.9 x	6.9	6.85	8.0	9.0
8.9	6.7	6.7	6.7 x	6.7	6.85	6.5	7.5
8.9	7.7	6.5	6.5 x	6.5	7.85	6.5	g2
	8.7	7.5	g1 x	7.5	8.85	7.5	7.5

# The Problem: Low- $h$ Bias

$f'$ -values,  $w = 1.5$  (reduced weight)

		8.7	7.7	6.7 x	S x	7.0

8.9	7.7	6.5 x	6.5 x	6.5 x	7.85	6.5 x	g2
	8.7	7.5	g1 x	7.5	8.85	7.5	7.5

# The Problem: Low- $h$ Bias

10 expanded states

29 generated states

between finding  $g_1$  and expanding right of  $S$

		8.7	7.7	6.7 x	S x	7.0	
		8.1	7.1 x				10.5
	7.9	6.9 x	6.9 x	6.9 x	6.85 x	8.0	9.0
8.9	6.7 x	6.7 x	6.7 x	6.7 x	6.85 x	6.5 x	7.5
8.9	7.7	6.5 x	6.5 x	6.5 x	7.85	6.5 x	g2
	8.7	7.5	g1 x	7.5	8.85	7.5	7.5

# Restarted Search

starting from scratch

$w = 1.5$

			7.7	6.7 x	S x	7.0	
			7.1				
							g2
			g1				

# Restarted Search

2 expanded state

5 generated states

before expanding right of S to find optimal path

			7.7	6.7 x	S x	7.0	
			7.1				
							g2
			g1				

# Insight

Continued search may be **biased** due to **early mistakes**:

- Greedy search: suboptimal area of search space
- Open list: many open states around previous goal
- Low  $h$ -value makes them look attractive
  - ⇒ Biased search explores suboptimal area in depth

Restarts overcome early mistakes of greedy search

## Related Work

Restarts used with **randomisation** in CSPs:

- Local search (Selman et al. 1992)
- Systematic search (Gomes et al. 1998)
- Purpose: undo bad random decisions (parameter choices)  
     $\rightsquigarrow$  escape barren areas of search space

We propose restarts for a deterministic, **A\*-type** algorithm

- Purpose: undo bad greedy decisions (low- $h$  bias)
- “Counter-intuitive” to throw away effort in best-first search with open list
- But: choice of nodes in open list is biased

# Restarting Weighted A\* (RWA\*)

RWA\*: **forget** open list between iterations:

- 1 Set weight and bound
- 2 **Clear open list, (re-)start from initial state**
- 3 Conduct WA\* search, using bound for pruning
- 4 Upon new best solution: report solution, goto 1.

Re-use previous search effort by

- Not re-calculating  $h$ -values of states seen previously
- Remembering best known paths to states

Extra cost: re-expansions. But expansions often cheap compared to evaluations (planning: 20% vs. 80%)

# Outline

- 1 Introduction
  - Anytime Weighted A\*
  - Low  $h$ -Bias
  - Restarting Weighted A\*
- 2 Experiments in Planning
- 3 Experiments in Other Domains
- 4 Summary

# Empirical Evaluation

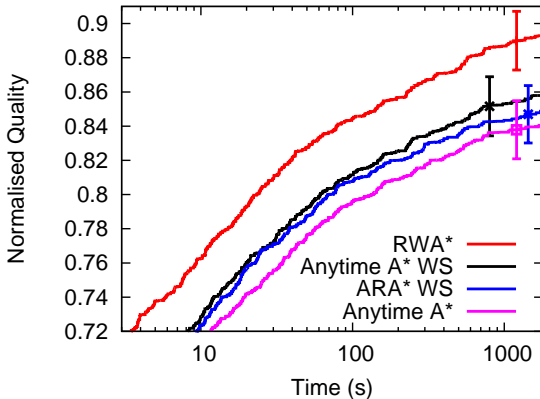

- Implemented in Fast Downward, using FF heuristic
- Replaced greedy BFS with anytime algorithms:
  - RWA\*
  - Anytime A\*
  - ARA\*
  - Beam-stack search
  - Window A\*
- Planner-specific **search enhancements** used (preferred operators, deferred evaluation)
- All 1612 classical tasks, 31 domains of IPCs 1–5

# Planning

WA\* methods much better than others; RWA\* best

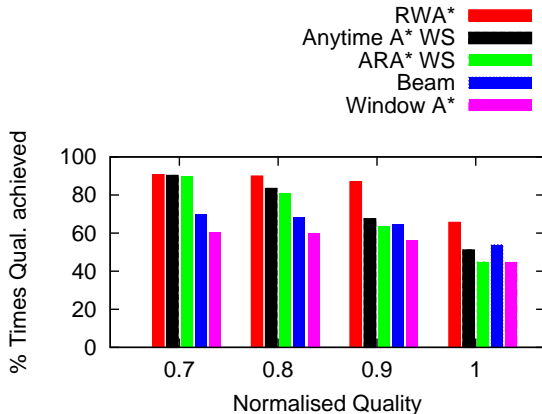

## Planning (cont.)

RWA\* > other WA\* methods in 40% of domains, rest on par

# Planning (cont.)

## Planning (cont.)

Without search enhancements, RWA\* dominant by smaller margin

## Planning (cont.)

Restarts change beginning of plan rather than end (Gripper #20):

# Outline

- 1 Introduction
  - Anytime Weighted A\*
  - Low  $h$ -Bias
  - Restarting Weighted A\*
- 2 Experiments in Planning
- 3 Experiments in Other Domains
- 4 Summary

# Robotic Arm

$RWA^* > \text{other } WA^* \text{ methods.}$

Beam-stack search and Window A\* very good here.

# Sliding-Tile Puzzle

RWA\*  $\approx$  other weight-decreasing WA\* methods.  
Window A\* very good here.

# A Controlled Experiment

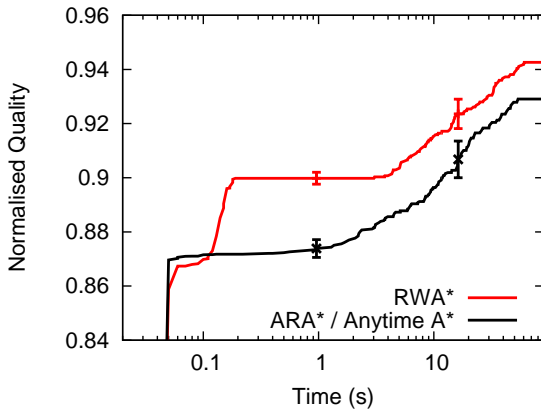

## Artificial search space

- Start state has **approx. goal distance** ( $agd$ )
- Random edge costs  $c$
- $agds$  of successors randomly differ from parent's by up to  $c$
- States with  $agd$  0 are goals
- Heuristic underestimates  $agd$  by certain percentage or less, where errors of parent and successors are **correlated**

## Finding:

- Restarts helpful if systematic heuristic bias present (i. e., if successors have **similar error** as parent)

## A Controlled Experiment (cont.)

# Outline

- 1 Introduction
  - Anytime Weighted A\*
  - Low  $h$ -Bias
  - Restarting Weighted A\*
- 2 Experiments in Planning
- 3 Experiments in Other Domains
- 4 Summary

# Summary

## RWA\* dominates other methods in planning

- In particular when search enhancements are used
- Restarts useful if greedy search is highly suboptimal
- E. g. if heuristics are systematically biased

## On par in other domains

- RWA\* always  $\geq$  other WA\* methods  
     $\rightsquigarrow$  even if restarts do not help, they do not hurt
- RWA\* always performs fairly well  $\rightsquigarrow$  robust,  
    while beam-stack search, Window A\* vary strongly

Undoing search effort can be worthwhile in anytime algorithms

Thank you!
